1. Given

$$f(x) = \frac{1}{\sqrt{(2\pi)^k |\Sigma|}} e^{-\frac{1}{2}(x-\mu)^T \Sigma^{-1}(x-\mu)},$$

where $x, \mu \in \mathbb{R}^k$, Σ is a k -by- k positive definite matrix and $|\Sigma|$ is its determinant.

Show that $\int_{\mathbb{R}^k} f(x) dx = 1$.

Since Σ is positive definite matrix, there exists unique lower-triangular L with positive diagonal s.t. $\Sigma = LL^T$

$$\text{let } y := L^{-1}(x-\mu) \Rightarrow x = \mu + Ly$$

$$\text{Then } (x-\mu)^T \Sigma^{-1}(x-\mu) = (Ly)^T (LL^T)^{-1}(Ly) = y^T y = \|y\|^2$$

The Jacobian of the transformation is $dx = |\det L| dy = \sqrt{\Sigma} dy$

$$\int_{\mathbb{R}^k} f(x) dx = \frac{1}{\sqrt{(2\pi)^k |\Sigma|}} \int_{\mathbb{R}^k} \exp\left(-\frac{1}{2}(x-\mu)^T \Sigma^{-1}(x-\mu)\right)$$

$$= \frac{1}{\sqrt{(2\pi)^k |\Sigma|}} \int_{\mathbb{R}^k} e^{-\frac{1}{2}\|y\|^2} |\det L| dy$$

$$= \frac{1}{\sqrt{(2\pi)^k |\Sigma|}} \int_{\mathbb{R}^k} e^{-\frac{1}{2}\|y\|^2} \sqrt{\Sigma} dy$$

$$= \frac{1}{(2\pi)^{\frac{k}{2}}} \int_{\mathbb{R}^k} e^{-\frac{1}{2}\|y\|^2} dy$$

$$\text{Since } \|y\|^2 = y_1^2 + y_2^2 + \dots + y_k^2, \quad e^{-\frac{1}{2}\|y\|^2} = \prod_{i=1}^k e^{-\frac{1}{2}y_i^2}$$

$$\int_{\mathbb{R}^k} f(x) dx = \frac{1}{(2\pi)^{\frac{k}{2}}} \int_{\mathbb{R}^k} e^{-\frac{1}{2}\|y\|^2} dy = (2\pi)^{-\frac{k}{2}} \prod_{i=1}^k \int_{-\infty}^{\infty} e^{-\frac{1}{2}y_i^2} dy$$

$$= \prod_{i=1}^k \underbrace{\int_{-\infty}^{\infty} \frac{e^{-\frac{1}{2}y_i^2}}{\sqrt{2\pi}} dy}_{=1} = 1 \quad *$$

2. Let A, B be n -by- n matrices and x be a n -by-1 vector.

(a) Show that $\frac{\partial}{\partial A} \text{trace}(AB) = B^T$.

(b) Show that $x^T A x = \text{trace}(x x^T A)$.

(b) Derive the maximum likelihood estimators for a multivariate Gaussian.

$$(a) \text{trace}(AB) = \sum_{i=1}^n (AB)_{ii} = \sum_{i=1}^n \sum_{j=1}^n A_{ij} B_{ji}$$

$$\frac{\partial}{\partial A_{pq}} \text{trace}(AB) = \frac{\partial}{\partial A_{pq}} \sum_{i=1}^n \sum_{j=1}^n A_{ij} B_{ji} = B_{qp}$$

$$\Rightarrow \frac{\partial}{\partial A} \text{trace}(AB) = B^T$$

$$(b) \text{trace}(x x^T A) = \sum_{j=1}^n \sum_{i=1}^n (x x^T)_{ji} A_{ij} = \sum_{j=1}^n \sum_{i=1}^n x_j x_i A_{ij} = \sum_{j=1}^n \sum_{i=1}^n x_i A_{ij} x_j$$

$$x^T A x = \sum_{i=1}^n \sum_{j=1}^n x_i A_{ij} x_j$$

$$\Rightarrow \text{trace}(x x^T A) = x^T A x$$

(c) Suppose we have i.i.d. sample $y_1, y_2, \dots, y_n \sim \mathcal{N}_K(\mu, \Sigma)$

where $\mu \in \mathbb{R}^K$ is the mean vector and $\Sigma \in \mathbb{R}^{K \times K}$ is the covariance matrix

$$\text{The PPF is } f(y|\mu, \Sigma) = \frac{1}{\sqrt{(\pi)^K |\Sigma|}} e^{-\frac{1}{2}(y-\mu)^T \Sigma^{-1}(y-\mu)}$$

$$\text{The likelihood function of the sample } L(\mu, \Sigma) = \prod_{i=1}^n f(y_i|\mu, \Sigma)$$

$$\text{Let } \ell(\mu, \Sigma) := \ln(L(\mu, \Sigma)) = -\frac{nK}{2} \ln(2\pi) - \frac{n}{2} \ln|\Sigma| - \frac{1}{2} \sum_{i=1}^n (y_i - \mu)^T \Sigma^{-1} (y_i - \mu)$$

$$\text{Let } \frac{\partial \ell}{\partial \mu} = 0 \Rightarrow \frac{\partial \ell}{\partial \mu} = \Sigma^{-1} \sum_{i=1}^n (y_i - \mu) = 0 \Rightarrow \hat{\mu} = \bar{y} = \frac{1}{n} \sum_{i=1}^n y_i$$

$$\ell(\hat{\mu}, \Sigma) = -\frac{n}{2} \ln|\Sigma| - \frac{1}{2} \sum_{i=1}^n (y_i - \bar{y})^T \Sigma^{-1} (y_i - \bar{y}) \quad (\text{Omitting the constant term does not affect the solution})$$

$$\sum_{i=1}^n (y_i - \bar{y})^T \Sigma^{-1} (y_i - \bar{y}) = \text{trace} \left(\Sigma^{-1} \sum_{i=1}^n (y_i - \bar{y}) (y_i - \bar{y})^T \right)$$

$$\text{Let } \bar{\Sigma} := \frac{1}{n} \sum_{i=1}^n (y_i - \bar{y}) (y_i - \bar{y})^T$$

$$\text{Rewrite } \ell(\hat{\mu}, \Sigma) : \ell(\hat{\mu}, \Sigma) = -\frac{n}{2} \ln |\Sigma| - \frac{n}{2} \text{tr}(\Sigma^{-1} \bar{\Sigma})$$

Using two matrix calculus identities

$$d \ln |\Sigma| = \text{tr}(\Sigma^{-1} d\Sigma) \quad , \quad d \text{tr}(\Sigma^{-1} \bar{\Sigma}) = -\text{tr}(\Sigma^{-1} \bar{\Sigma} \Sigma^{-1} d\Sigma)$$

$$\text{We have } d\ell = -\frac{n}{2} \text{trace}(\Sigma^{-1} d\Sigma) + \frac{n}{2} \text{trace}(\Sigma^{-1} \bar{\Sigma} \Sigma^{-1} d\Sigma)$$

$$= \langle G, d\Sigma \rangle \quad \text{where } G = -\frac{n}{2} \Sigma^{-1} + \frac{n}{2} \Sigma^{-1} \bar{\Sigma} \Sigma^{-1}$$

$$\text{The first-order condition } G = 0 \Rightarrow -\frac{n}{2} \Sigma^{-1} + \frac{n}{2} \Sigma^{-1} \bar{\Sigma} \Sigma^{-1} = 0$$

$$\Rightarrow \Sigma^{-1} \bar{\Sigma} \Sigma^{-1} = \Sigma^{-1}$$

$$\Rightarrow \bar{\Sigma} = \Sigma$$

$$\Rightarrow \hat{\Sigma} = \bar{\Sigma}$$

$$\text{Final Result : } \hat{\mu} = \frac{1}{n} \sum_{i=1}^n y_i \quad , \quad \hat{\Sigma} = \frac{1}{n} \sum_{i=1}^n (y_i - \hat{\mu})(y_i - \hat{\mu})^T$$

3 Unanswered Questions :

上課有說到啟動函數用 $\sigma(x) = \frac{1}{1+e^x}$ 的原因. 那若用其他函數

做為啟動函數會有什麼影響?
